

Old and New Benchmarks for Relative Termination of String Rewrite Systems

Dieter Hofbauer¹, Johannes Waldmann²
¹ASW Saarland (Germany), ²HTWK Leipzig (Germany)

19th Workshop on Termination
 Obergurgl, Austria, August 24–25, 2023

1/11

Relative Termination (Definition, Example)

- # SRS_Relative/Zantema_06/rel11
 (RULES $bpb \rightarrow bapb$, $p \rightarrow apa$, $apaa \rightarrow p$)
- is shorthand for pair of rewrite systems
 $R = \{bpb \rightarrow bapb\}$, $S = \{p \rightarrow apa, apaa \rightarrow p\}$
- relation \rightarrow_R relative to relation \rightarrow_S : $\rightarrow_R / \rightarrow_S := \rightarrow_R \circ \rightarrow_S^*$
- Def: R terminates relative to S iff $SN(\rightarrow_R / \rightarrow_S)$, Notation $SN(R/S)$
 each (infinite) mixed derivation contains only finitely many R steps
- ref: Jan Willem Klop 1987, Alfons Geser 1990, Hans Zantema 2004
- application: removal of rules (D) in modular absolute termination proofs
 $SN(D/R) \wedge SN(R \setminus D) \Rightarrow SN(R)$
- application: rewriting modulo equations
- our contribution: discuss current TPDB/SRS-Relative benchmarks, discuss some methods for solution, provide new small benchmarks
- (COMMENT [rel11] invariant after first rule:
 left from p more a 's than right from p)

2/11

How to win SRS-Relative, by ignoring “-Relative”

- termcomp 22, SRS-Relative, winner: MultumNonMulta, 203 YES.
- $SN(R \cup S) \Rightarrow SN(R/S)$. we present: the *strictify* transformer:
 consider weak rules as strict, prove absolute termination: 211 YES.
- due to benchmarks ICFP-2010, Waldmann-19
- if $SN(S)$, then $SN(R/S) \iff SN(R \cup S)$
- only in case $\neg SN(S)$ do we need specific proof methods for $SN(R/S)$.
- actual matchbox (2023) strategy expression (strat/combi.strat)

```
let { standard = ... ; relative = ... ; ... }
in Apply cleaner (Or_Else done (Apply weights (Or_Else done
(Or_Else
  (Apply (When_True (Apply dropstrict
    (Apply strictify standard)))
  (Apply strictify standard)))
relative
  )))
```

3/11

Relative Non-Termination

- the obvious method is to find a loop $w (\rightarrow_R / \rightarrow_S)^+ pwq$
- one specific method (R -emitting loops, AProVE TC 22) is:
 if S admits a loop $w \rightarrow_S^+ pwq$ such that p or q contains an R -Redex,
 then $\neg SN(R/S)$.
 in this case, right-hand sides of R do not matter!
- (Geser, Zantema 1999) for absolute termination:
 R admits loop $\iff R$ admits looping forward closure (FC)
- not true for relative termination:
 example: $\{bab \rightarrow a, c \rightarrow cb, d \rightarrow bd\}$
 has loop $cad \rightarrow^2 cbabd \rightarrow cad$ but no looping FC
- given loop is overlap closure (OC).
 cf. role of FC/OC in *sparse tiling* for absolute/relative termination.
 OCs are more expensive to enumerate than FCs

4/11

Relative Termination: When in doubt—use brute force

- that is, matrix interpretation via SAT encoding (ersatz, kissat)
- arctic (below zero) matrix int. for Zantema-06/rel11 (open in TC 22)
 $\{bpb \rightarrow bapb, p \rightarrow apa, apaa \rightarrow p\}$,

5/11

Relative Termination: When in doubt—...

- Zantema-06/rel12: $\{bpb \rightarrow abapba, p \rightarrow apa, apaa \rightarrow p\}$,
- natural matrix interpretation

$$a = \begin{pmatrix} 1 & \dots & \dots & \dots \\ \dots & 1 & \dots & \dots \\ \dots & \dots & 1 & \dots \\ \dots & 1 & \dots & \dots \\ \dots & \dots & \dots & 1 \end{pmatrix}, b = \begin{pmatrix} 1 & 1 & \dots & \dots \\ \dots & 1 & 4 & \dots \\ \dots & 1 & \dots & \dots \\ \dots & 2 & \dots & \dots \\ \dots & \dots & \dots & 1 \end{pmatrix}, p = \begin{pmatrix} 1 & \dots & \dots & \dots \\ \dots & 1 & \dots & \dots \\ \dots & \dots & 1 & \dots \\ \dots & \dots & \dots & 1 \end{pmatrix}$$

- how is the previous related to this arctic matrix interpretation:

$$a = \begin{pmatrix} 0 & \dots & \dots & \dots \\ \dots & -1 & \dots & \dots \\ \dots & \dots & 0 & \dots \\ \dots & \dots & \dots & 0 \end{pmatrix}, b = \begin{pmatrix} 0 & \dots & 0 & \dots \\ 1 & 2 & -1 & \dots \\ \dots & 0 & \dots & \dots \\ \dots & -1 & \dots & \dots \\ \dots & \dots & 0 & \dots \end{pmatrix}, p = \begin{pmatrix} 0 & \dots & \dots & \dots \\ \dots & 2 & \dots & \dots \\ \dots & 0 & \dots & \dots \\ \dots & \dots & 1 & \dots \\ \dots & \dots & \dots & 0 \end{pmatrix}$$

6/11

Where brute force does not help (so far)

- (remains open) Zantema-06/rel03:
 $\{ac \rightarrow cca, c \rightarrow baab, baab \rightarrow c\}$
 is related to $a(baab) \rightarrow (baab)^2a$, which is RFC-matchbounded.
- (remains open) Zantema-06/cars
 (RULES $Mr R \rightarrow Ml cr R$, $L Ml \rightarrow L Mr cr$
 $, Mr o \rightarrow Ml cr$, $Mr n \rightarrow Ml cr$, $o Ml \rightarrow Mr cr$, $n Ml \rightarrow Mr cr$
 $, Mr o \rightarrow= Mr$, $Mr n \rightarrow= Mr$, $o Ml \rightarrow= Ml$, $n Ml \rightarrow= Ml$
 $, Ml cr \rightarrow= cl Ml$, $Mr cr \rightarrow= cl Mr$, $L \rightarrow= L n$, $R \rightarrow= n R$
 $, cr n \rightarrow= n cr$, $cr o \rightarrow= o cr$, $cr o \rightarrow= o$
 $, n cl \rightarrow= cl n$, $o cl \rightarrow= cl o$, $o cl \rightarrow= o$)

7/11

Brand New: Small(est) Hard Relative SRS

- most small TPDB benchmarks are solved—then what next?
- make a complete enumeration by size, filter w.r.t. current provers
- cf. enumerations for SRS-absolute:
 - ▶ one-rule: Kurth (1990), Geser (2002), Wenzel-16,
 - ▶ many-rule: Waldmann-07
- fresh relative SRS: Waldmann-23, smallest unsolved:
 - ▶ alphabet 3: size 7
 (RULES $a c \rightarrow c$, $\rightarrow= a b$, $a b \rightarrow=$)
 (RULES $a c \rightarrow c$, $\rightarrow= a b$, $b a \rightarrow=$)
 up to size 8: 41 benchmarks, 34 unsolved
 - ▶ alphabet 2: size 9
 (RULES $a a b b a \rightarrow$, $\rightarrow= a b a b$)
 up to size 10: 57 benchmarks, 13 unsolved
- NB: starexec could run such enumerations/filterings all year long. . .

8/11

Two New benchmarks, with Manual Proofs

- (RULES $a \ c \rightarrow c$, $\rightarrow = a \ b$, $a \ b \rightarrow =$)
hand-waving: number of un-matched a is reduced
exact: this number is first component of interpretation

$$\begin{aligned}a_I(x, y) &= \text{if } y > 0 \text{ then } (x, y - 1) \text{ else } (x + 1, 0) \\b_I(x, y) &= (x, y + 1) \\c_I(x, y) &= (x, 0)\end{aligned}$$

is monotone w.r.t. order $(x_1, y_1) > (x_2, y_2)$ iff $x_1 > x_2 \wedge y_1 = y_2$

- (RULES $a \ c \rightarrow c$, $\rightarrow = a \ b$, $b \ a \rightarrow =$)
use the very same interpretation as above, but with order:
 $(x_1, y_1) > (x_2, y_2)$ iff $(x_1 > x_2) \wedge (y_1 \geq y_2) \wedge (x_1 - y_1 > x_2 - y_2)$
 $(x_1, y_1) \geq (x_2, y_2)$ iff $(x_1 \geq x_2) \wedge (y_1 \geq y_2) \wedge (x_1 - y_1 \geq x_2 - y_2)$
- is this semantic labeling w.r.t. a (quasi) model over \mathbb{N} ? see also Hofbauer WST'18.

9 / 11

Conclusion/Discussion

- Retire/Relabel SRS-Relative/{ICFP-10,Waldmann-19}?
 - ▶ keep in TPDB but don't use in competition
 - ▶ OTOH, do use, but de-value?
- new small hard SRS:
 - ▶ solve them,
 - ▶ devise new methods to automatically solve them
- certified relative termination?
CPF/CeTA currently has all we need, except for:
 - ▶ sparse tiling, with overlap closures (has full tiling)and these methods for absolute termination, needed after `strictify`:
 - ▶ RFC (approximated) matchbounds (has full matchbounds)
 - ▶ sparse tiling, with forward closuresso ... I am starting a project *verified SRS termination in Agda*

10 / 11

Questions asked after the talk

- Danger: notation in the paper is misleading: uses ϵ in two meanings:
 - ▶ in rule: $\epsilon \rightarrow = ab$, translated into TRS rule $x \rightarrow = a(b(x))$
 - ▶ in interpretation: $\epsilon_I = (0, 0)$, epsilon denotes the nullary symbol in the leaf of a term (tree) that encodes a string (abc encoded as $a(b(c(\epsilon)))$)
- Q: Do you have a theorem about " R/S is looping $\iff R/S$ has a looping overlap closure"?
- A: No. — We have (FSCD19)
" $\text{SN}(R/S) \iff \text{SN}(R/S, \text{ROC}(R \cup S))$ " (for relative termination, it is enough to consider mixed derivations starting from right-hand sides of overlap closures)
- Q: Kissat over Minisat—did you measure?
- A: I guess I did but I did not take detailed notes.
- Q: Why the new solutions (rel11, rel12)?
- A: change in proof search strategy. Matchbox has too many moving, and moveable parts. Changes in strategy expression may have unforeseen consequences.
